DETECTION OF PREVIOUS SECTION FAIL FOR A TRANSPARENT TRIBUTARY

5 **BACKGROUND OF THE INVENTION**

Field of the Invention

The invention is directed to communication systems that transport signals of an arbitrary data format via a standard synchronous format, and more particularly to detecting operation parameters for the
10 previous section of such communication systems.

Background Art

Increasing deployment of optical fiber transmission systems with large cross-sections supported on a few strands of fiber have
15 increased concern about survivability and management of such large optical networks. In addition to the growing size of the networks, the speed of the signals increases, as they evolve from analog to digital and from voice to data and video.

Evolution of the current transport networks is hindered by a
20 number of constraints. For example, the networks operate according to fiber specific transmission protocols, each having different levels of operation, administration, maintenance and provisioning (OAM&P) functionality, so that the nodes must be equipped with protocol-specific hardware and software. In addition, handling a plurality of protocols at
25 speeds over 100Mb/s poses real problems to current generation of microprocessors.

One way to increase the speed (and bandwidth) of the network is to replace the electronics components with optical components. The increased transport capacity requirements are also meet by the
30 introduction of point to point optical fiber systems, carrying TDM signals. An example of a TDM network is SONET/SDH, which transports hierarchically multiplexed lower rates tributaries into a higher rate TDM signal. SONET/SDH is a physical layer technology which is currently used

as a transport service for ATM, SMDS, frame relay, T1, E1, etc. SONET/SDH provides the ability to combine and consolidate traffic from different locations through one facility (grooming), and reduces the amount of back-to-back multiplexing. More importantly, network providers can

5   reduce the operation cost of their transmission network by using the comprehensive OAM&P features of SONET. For a service, being able to be easily transported by a SONET/SDH network is a valuable attribute, since the network provider can make use of the large base of installed SONET-compatible equipment.

10   On the other hand, the SONET/SDH network is designed for certain tributary rates only, so that in many cases a user signal needs to undergo a mapping operation to be able to be transported by SONET/SDH. For example, Bellcore TR-0253 describes in detail standard mappings of common asynchronous transmission formats such as DS0,

15   DS1, DS2, DS3, into SONET. Similar mappings are defined for the ETSI hierarchy mapping into SDH.

There are other standards or proprietary schemes that allow transportation of a very specific set of signals, with format specific hardware and hardware for processing the maintenance information.

20   These methods of mapping cannot be used to map rates that vary significantly from the standard, and a different hardware is generally required to perform the mapping for each type of signal.

The speed and bandwidth of the communication networks has been further increased by the introduction of the optical network layer with

25   optical switching (WDM network), controlled through a network management system. Such an optical layer could be made transparent to data rates and formats.

In addition, there is a current trend to unify the transmission protocols, for creating an open, transparent transport network that uses

30   common equipment and software. Ideally, such a protocol and bit rate transparent transport network needs to provide appropriate mechanisms for delivering the client signals at the far end with minimal cost and with enough OAM&P information for allowing error correction. Due to the

advantages listed above, adapting SONET/SDH protocols to the transparent transport network appears to be the solution of choice.

Patent Application SN 09/349,086 (Roberts), entitled Mapping Arbitrary Signals into SONET, filed on July 8, 1999 and assigned to Nortel
5   Networks Corporation discloses an efficient method and a synchronizer for mapping arbitrary signals into SONET such that the signals can be recovered with low timing jitter at low cost at the far end. This mapping method can be used for tributaries of almost any continuous format. The synchronizer could recognize selected protocols, frame on them, and do
10   the corresponding performance monitoring.

However, protocols not known to the manufacturer, or not yet defined, cannot be recognized with prior art mapping methods. Furthermore, performance monitoring is still a major unresolved technical problem when designing a transparent tributary, particularly at signal rates
15   higher 100MB/s, which are generally too fast for a microprocessor to perform measurement functions.

Of major importance is detecting the previous section fail. As the name suggests, previous section fail indicates if a signal was degraded over the last section of the network, or upstream, over the
20   previous section. For example, most service providers need positive evidence if a problem occurred outside their network (in the received signal), or within their network. Specifically, if a user experiences performance problems on the signal that it receives, the service provider has to be able to determine if the signal was degraded when initially
25   passed to it, or if the problems are in its network.

Bellcore TR-00253 Issue 6 provides for determination of previous section fail for SONET. No recommendations are yet available for transparent tributaries.

30   **SUMMARY OF THE INVENTION**

It is an object of this invention to provide a transparent tributary mapping system with a means for performance monitoring of the previous section.

According to one aspect of the invention, there is provided a transparent port for a high rate network comprising, a receiver unit for receiving an incoming signal of an arbitrary data rate R1 and extracting a user signal and a data clock, a programmable link termination PLT for

5 reporting a set of performance parameters for said incoming signal, and a processing unit for recognizing a plurality of provisioned protocols, selecting a first protocol characterizing said incoming signal and configuring said PLT according to said first protocol.

According to a further aspect of the invention there is also

10 provided transparent port for a high rate network comprising, a programmable link instigation PLI for reporting a set of performance parameters for a data signal of an arbitrary rate R1', a processing unit for recognizing a plurality of provisioned protocols, selecting a first protocol characterizing said data signal and configuring said PLI according to said

15 first protocol, and a transmitter unit connected to said PLI for launching an outgoing signal of said first protocol, comprising user information within said data signal.

According to yet another aspect of the invention, there is further provided a method for transmitting a continuous digital signal of an

20 arbitrary rate R1 over a synchronous network as a transparent tributary, comprising, at a transmit terminal, selecting a container signal of a rate R, higher than said rate R1, detecting the rate R1 of said continuous digital signal and determining a first protocol corresponding to said rate R1, measuring according to a first protocol a set of performance parameters

25 on said continuous signal and reporting said set of performance parameters, and translating said set of performance parameters from said first protocol to a second protocol characterizing said container signal and providing said translated set into said container signal.

Advantageously, the invention provides a rather simple

30 solution for detection of OAM&P parameters, such as e.g. the previous section fail, for signal rates at 10Gb/s or higher.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other objects, features and advantages of the invention will be apparent from the following more particular

5   description of the preferred embodiments, as illustrated in the appended drawings, where:

Figure 1 is the functional block diagram of a transparent port; and

Figure 2 shows the functional block of a single data flow

10   through a bidirectional transparent port, according to an embodiment of the invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

For the purpose of this invention, a transparent port is a data

15   terminal which maps, and respectively reverse maps, data of arbitrary rates R1 into, and respectively from, a synchronous container of rate R. Term 'arbitrary' is used for rates R1 of the incoming signal in the range of ± 20% of the port clock, and a variety of formats. "Format' or 'protocol' is used to define the type of the signal, such as SONET OC-N, 1GE, DS-n,

20   etc.

The configuration of such transparent ports **1** and **2** is illustrated in Figure 1 and described in the co-pending Patent Application 09/349086, which is incorporated herein by reference. To summarize, transparent port **1,** or synchronizer at site **A**, maps a continuous signal S_j

25   received from a local user into a SONET container of an appropriate size, and transmits the container to a far end transparent port **2** at site **B**, over an optical transport network **5**. For the purpose of this invention, a local user is a terminal, or an access network, etc. For example, network **5** may be a short reach optical network which operates at 1310 nm.

30   The transparent port **2** recovers the SONET signal received from site **A**, extracts (reverse maps) the continuous format signal from the SONET container, and provides it to the local user at site **B**. Similar transparent ports may be provided for parallel mapping of more signals,

shown as S_1 to S_n. In addition, the data terminal at site **A** may comprise one or more transparent receive ports, or de-synchronizers, as is transparent port **2** shown at site **B**.

    At the transmit side, the size of the container for each signal S_j

5   is selected in software, so as to provide a satisfactory bandwidth usage for a large range of continuous format signals. For example, if a nxSTS-12 is used for the envelope, n is between four and twenty for a high speed version of the synchronizer, and between one and five for a medium speed version. Use of the lower speed version for lower rates avoids

10   stranding significant network capacity.

    The synchronizer comprises a receiver unit **15** equipped with a receiver **11** and a flexible clock recovery unit **13** which recovers data **12** from the input signal S_j. It is to be understood that site A could be equipped with signal converters (not shown) if the input signal is not in

15   electronic format. Flexible clock recovery unit **13** could be for example the frequency agile PLL disclosed in the US patent application "Apparatus and Method for Versatile Communication" (Habel et al), SN 09/218053, filed 22 December 1998, and assigned to Nortel Network Corporation. The design of the flexible clock recovery unit **13** allows recovery of a broad continuous

20   range of bit-rates, with practically no conceptual limit on the range.

    The data bits of the input signal S_j are mapped into the respective SONET frame with evenly interspersed fixed stuff bits and adaptive stuff bits by a mapping unit **20**. A mapping unit **20** divides the frame of S_j into evenly sized blocs, and determines the number of fixed

25   stuff bits for each block. Since the rate of the signal S_j is not known in advance, the number of the variable stuff bits is determined on the go, based on a function β which gives information about the phase difference between the two clocks.

    Mapping unit **20** comprises a flexible buffer **21** and a mapper **23**.

30   Buffer **21** generates β during processing of the current block, and this β is used for mapping of the next block. The value of β gives the position of the variable stuff bits and the number of the valid bits in the

next block. Buffer **21** receives the bits of a block at the recovered clock rate and transmits the bits to the mapper at the rate of a gapped clock **16**. Gapped clock **16** is derived from the SONET clock **24**, and is discontinued at appropriate phase instances. The discontinuities (gaps) are given by

5   β and by the number of fixed stuff bits.

The mapper **23** defines a valid location, which is a location for a data bit, and an invalid location, which is a location for a stuff bit, and provides an output signal **12'** with the stuff bits (fixed and variable) distributed uniformly within the frame.

10   After the mapping operation, block **25** places the path overhead (POH) information into the appropriate fixed stuff bit positions, and the time slot interchange unit **30** re-arranges the POH bits in the frame so that SONET/SDH equipment in the optical network **5** can recognize the frame. Signal S_j' is then converted into an optical signal O_j'

15   which is transmitted towards terminal **2** over network **5**. The circuits involved in the transmission of the signal are generally referred to as transmission equipment **6**.

The de-synchronizer effects the reverse operation by absorbing the fixed stuff bits and the adaptive stuff bits to regenerate O_j.

20   The de-synchronizer receives the respective O_j' signal, and recovers the data S_j' in electrical format by receive equipment generally designated by **7**. The time slot interchange unit **30'** and the POH demultiplexer **25'** extract the POH information from the corresponding timeslots using SONET clock **24**, and provide signal **12'** with the data and stuff bits to a

25   reverse mapping unit **20'**. Reverse mapping is performed in reverse mapper **23'** based on β and SONET clock **24** available locally. Buffer **21'** receives signal **12'** at the rate of gapped clock **16**, while data is extracted from the buffer at the rate of the data clock **14**. Transmit unit **15'** receives the signal with the original proprietary protocol and data rate, and

30   transmits O_j to the local client in optical format. Depending on the user particulars, means for converting the signal may also be provided at site B.

For example, if the user is an optical access network, S_j will be converted to an optical format.

β, which is determined at site A during the mapping operation, is communicated to site B for the reverse mapping. Similarly, clock **14**

5 and frame rate are signalled to site **B** from site **A**.

Figure 2 shows the functional block diagram of a bidirectional transparent port with detection of the previous section parameters capability according to the invention. Signal processing in the transmit direction involves a synchronizer **3** which maps the user signal S_{in} of an

10 arbitrary rate R1 into a synchronous signal S_{out} of a standardized rate R, and transmit the optical variant O_{out} over an optical transport network **5**. Signal processing in the receive direction involves a de-synchronizer **4** which performs a reverse mapping operation to recover the user signal S_{out}' of rate R1' from a synchronous signal O_{in}' of rate R', received from

15 the optical transport network **5**. It is evident that a transparent port with a de-synchronizer similar to **4** must be provided at the far end for reverse mapping signal S_{in} from synchronous signal S_{out}. Also a transparent port with a synchronizer as shown at **3** could present at the same or at a different transparent port for mapping Sout' into O_{in}'.

20 The description is provided assuming that the signals are mapped into a SONET/SDH format, which are extensively used for high rates. Nonetheless, the synchronizer **3** and de-synchronizer **4** may operate using non-SONET/SDH formatted signals. In addition, Figure 2 illustrates a transmission equipment block **6** and a receive equipment

25 block **7** at the interface with the optical network **5**, which perform general transmit and receive functions. For example, block **6** is involved in launching the signal over network **5** and may include multiplexers, TOH processors, TDM or WDM devices, long- reach transmitters, modulators, etc. Similarly, block **7** is involved in receiving the signal from the network

30 **5** and may include de-multiplexers, TOH processors, TDM or WDM devices; etc. Furthermore, Figure 2 does not show all units on the user sides.

Transparent port **3** includes a receiving unit **15** which identifies the bit rate R1 of an incoming signal S_{in} presented to it, using a flexible clock recovery unit, as shown in Figure 1. Receiving unit **15** recovers the user signal **12** from the incoming signal based on the recovered data clock

5   **14**.

The transparent port **3** is also provided with a microprocessor **100**. The microprocessor **100** examines clock rate information received from the receiving unit **15**, and determines the protocol of the incoming signal S_{in}, corresponding to that data rate. Based on this determination,

10   the microprocessor **100** selects the logic configuration for a programmable link termination unit PLT **10**. PLT **10** is then configured according to this protocol.

New protocols may be subsequently added to the microprocessor **100**, as they emerge.

15   PLT **10** is inserted between the receiving unit **15** and a mapping unit **20**. PLT unit **10** could be a field re-programmable gate array, or could be another programmable circuit. The PLT **10** performs the functions specific to the protocol corresponding to bit rate R1 if it exists, or passes through the signal for unanticipated clock rates. PLT **10**

20   may perform framing, error counts, code conversion, may corrects parity, and may perform other performance monitoring actions specific to the protocol on the input signal S_{in}.

For example, if rate R1 of signal **12** is that of a video signal, or identifies a gigabit Ethernet, an OC-N, or any other signal, the PLT **10**

25   frames on that signal, computes and reports performance parameters, and removes any line coding.

If rate R1 of signal **12** is that of a recognized wrapped signal, PLT **10** frames on the wrapper, computes and reports performance parameters, and removes the wrapper.

30   If rate R1 of signal **12** is not recognized, the signal is passed through, and the PLT reports a minimal set of performance monitoring parameters, such as e.g. optical signal strength, clock continuity, jitter and clock rate.

Signal **12'**, herein called a data signal, is provided by PLT **10** to a mapping unit **20**, which maps the data into an STS-N synchronous payload envelope, shown at **12"**. As indicated above, SONET/SDH technology is used by way of example, other technologies may be equally

5 employed. In this specification, the synchronous signal is also defined as a container signal, in that it contains the user signal, mapped into a fixed length container according to the mapping algorithm of mapping unit **20**.

The POH (path overhead) information is multiplexed into the relevant fixed stuff bits by multiplexer **25**, and the STS-N is passed to the

10 time slot interchange block **30** for cross-connection and transmission over the back-plane. Block **30** re-arranges the fixed stuff bits with the POH information into the time-slots recognized by the SONET/SDH equipment of network **5**.

In the embodiment of Figure 2, the signal S_{out} is converted to

15 an optical format O_{out} by transmission equipment **6**, and thereafter launched towards its destination over the high speed network **5**.

In another embodiment, the PLT **10** could be off-line, to avoid delays in the start of transmission, in which case it could not perform coding changes or parity correction.

20 In the receive direction, a signal O_{in}' of a standard rate R', received from high speed network **5** in optical format is converted to an electronic format by receive equipment **7**. If network 5 is a SONET?SDH network, O_{in}' is a signal formatted according to the SONET/SDH protocol. A time slot interchange unit **30'** rearranges (crossconnects) the fixed stuff

25 bits with the POH information in the time-slots recognized by a reverse mapping unit **20'**. The path performance monitoring bytes are extracted from the respective timeslots in POH demultiplexer **25'**, and the performance parameters are computed and used in the known way.

A reverse mapping unit **20'** reverse maps the container signal

30 **22"** to its original format. Unit **20'** receives the signal **22"** from demultiplexer **25'**, and also receives SONET clock **24** and function β, and outputs the data signal **22'** at the rate of the data clock **14**. Data clock **14**

and function β are received over network 5 through signalling, while the SONET/SDH clock is available locally. Function β gives to the reverse mapping unit 20' the size of the block, information about the phase difference between the data clock and the SONET/SDH clock

5   accumulated over the current block and the number of the valid bits in the next block.

The data signal 22' is then applied to a programmable link instigation unit PLI 10'. PLI 10' is configured by microprocessor 100 according to the protocol for user signal 22 corresponding to bit rate R1 if

10   it exists, or passes through the signal for unanticipated clock rates. PLI 10' may perform framing, error counts, code conversion, may corrects parity, declare alarms, and may perform other performance monitoring actions specific to the protocol of the output signal S_{out}', as well as specific reporting whenever requested by the user.

15   For example, PLI 10' performs one of the following functions in a manner specific for user signal S_{out}':

If rate R1' of signal S_{out}' is that of a video signal, or identifies a gigabit Ethernet, an OC-N, etc, the PLI 10' frames the signal, computes and reports performance parameters, and adds the respective line coding.

20   If rate R1' of signal S_{out}' is that of a recognized wrapped signal, PLI 10' frames on the wrapper, reports performance parameters, and adds the required wrapper. The PLI 10' also co-ordinates generation of the fractionally higher clock rate by the frequency agile transmitter 15'.

If the rate R1'is not recognized, the signal is passed through,

25   and PLI 10' reports a reduced set of performance monitoring parameters such as clock continuity, jitter and clock rate.

The user signal 22 is sent to a frequency agile transmitter unit 15' which provides S_{out}' to the user in the format of choice.

It is also to be appreciated that the rates R1 and R1' (and the

30   corresponding rates R and R') could be the same or different.

The size N of the synchronous envelope can be pre-provisioned by the user. For example, N could be between 2 and 60 for a low speed variant of the transparent terminal which is used for speeds

between 100MB/s and 3Gb/s. N could be a multiple of 12 between 48 and 240 for a high speed variant, which is used for speeds between 2GB/s and 13Gb/s.

While the invention has been described with reference to particular example embodiments, further modifications and improvements which will occur to those skilled in the art, may be made within the purview of the appended claims, without departing from the scope of the invention in its broader aspect.
